| 1 | <b>ExitSelfRef: exit self refresh (after suspend to RAM or for DRAM training) command.</b> Read, write-1-only; cleared-by-hardware. Reset: 0. Writing a 1 to this bit causes the DRAM controller to bring the DRAMs out of self refresh mode. It also causes the DRAM controller to issue ZQCL and MRS MR0 commands. This command should be executed by BIOS when returning from the suspend to RAM state, after the DRAM controller configuration registers are properly initialized, or when self refresh is used during DRAM training. This bit is read as a 1 while the exit-self-refresh command is executing; it is read as 0 at all other times. This bit should not be set if the DCT is disabled. |

**D18F2x98\_dct[3:0] DRAM Controller Additional Data Offset**

Reset: 8000\_0000h. See 2.9.3 [DCT Configuration Registers].

Each DCT includes an array of registers that are used primarily to control DRAM-interface electrical parameters. Access to these registers is accomplished as follows:

- Reads (without auto-increment):

1. Write the register number to [D18F2x98\\_dct\[3:0\]\[DctOffset\]](#) with [D18F2x98\\_dct\[1:0\]\[DctAccessWrite, DctOffsetAutoIncEn\]](#)={0,0}.
2. Read the register contents from [D18F2x9C\\_dct\[3:0\]](#).

Writes (without auto-increment):

1. Write all 32 bits of register data to [D18F2x9C\\_dct\[3:0\]](#) (individual byte writes are not supported).
2. Write the register number to [D18F2x98\\_dct\[3:0\]\[DctOffset\]](#) with [D18F2x98\\_dct\[3:0\]\[DctAccessWrite, DctOffsetAutoIncEn\]](#)={1,0}.
  - The data will be delivered to the phy similar to a posted memory-write, and the write will complete without any further action. However, to ensure that the contents of the array register write have been delivered to the phy, software issues a subsequent configuration register read or write to any register in the northbridge. For example, reading [D18F2x98\\_dct\[3:0\]](#) will accomplish this.

- Reads (with auto-increment):

1. Write the first register number to [D18F2x98\\_dct\[3:0\]\[DctOffset\]](#) with [D18F2x98\\_dct\[1:0\]\[DctAccessWrite, DctOffsetAutoIncEn\]](#)={0,1}.
2. Read the register contents from [D18F2x9C\\_dct\[3:0\]](#).
3. Repeat step 2 as needed for each additional array register read.
4. Program [D18F2x98\\_dct\[3:0\]\[DctOffsetAutoIncEn\]](#)=0.

Writes (with auto-increment):

1. Write the first register number to [D18F2x98\\_dct\[3:0\]\[DctOffset\]](#) with [D18F2x98\\_dct\[3:0\]\[DctAccessWrite, DctOffsetAutoIncEn\]](#)={1,1}.
2. Write all 32 bits of register data to [D18F2x9C\\_dct\[3:0\]](#).
3. Repeat step 2 as needed for each additional array register write.
4. Program [D18F2x98\\_dct\[3:0\]\[DctOffsetAutoIncEn\]](#)=0.

| 3:0   | <b>FineDlyCtrl: Fine delay control.</b> Read-write. Specifies an untimed amount of delay that the DATA (includes both DQ and DQS/WCK) chiplet signals are delayed from the default setup time, in addition to the per-group DLL RxDly. When applied to a CSR for a data strobe pad, then this has the equivalent functionality of legacy receiver enable delay. When applied to a CSR for a DQ pad, then this has the equivalent functionality of legacy read DQS delay.<br><table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>0h</td><td>Minimum delay</td></tr> <tr> <td>9h</td><td>Maximum delay</td></tr> <tr> <td>Fh-Ah</td><td>Reserved</td></tr> </table> | Bits | Description | 0h | Minimum delay | 9h | Maximum delay | Fh-Ah | Reserved |

| 7:0  | <b>RxDly: Rx delay.</b> Read-write. BIOS: See 2.9.9.2.10. Specifies the time that the DATA (includes both DQ and DQS/WCK) chiplet signals are delayed from the default setup time, in increments of 1/32UI. When applied to a CSR for a data strobe pad, then this has the equivalent functionality of legacy receiver enable delay. When applied to a CSR for a DQ pad, then this has the equivalent functionality of legacy read DQS delay. |

**D18F2x9C\_x0[F,1:0][F,8:0]1\_[F,9:0][F,3:0]81\_dct[3:0] Tx Delay**

Cold reset: 0000\_0000h. See 2.9.4.1 for chiplet to pad mapping and see 2.9.4 for pad to pin mapping.

| 7:0  | <b>TxDly: Tx delay.</b> Read-write. BIOS: See 2.9.9.2.10. Specifies the time that the DATA (includes both DQ and DQS/WCK) chip signals are delayed from the default setup time, in increments of 1/32 UI. When applied to a CSR for a write strobe pad, then this has the equivalent functionality of legacy write DQS delay. When applied to a CSR for a DQ pad, then this has the equivalent functionality of legacy write data delay. |

Cold reset: 0000\_0400h.

Table 178: Index Mapping for PLLMultDiv Value Definition

| Bits  | Data Rate |
|-------|-----------|
| 0603h | 667 MT/s  |
| 0D01h | 1333 MT/s |
| 1000h | 1600 MT/s |
| 1203h | 1866 MT/s |
| 1501h | 2133 MT/s |
| 1800h | 2400 MT/s |
| 2000h | 3200 MT/s |
| 2200h | 3400 MT/s |

Note: “Memory-Clock” frequency is one-half of the data rate for DDR3.

| Bits  | Description                                                                                                                                                                                                                    |

| 3:0         | <p><b>PMUClkDiv: PMU CLK divider.</b> Read-write. BIOS: <a href="#">2.9.9.2.3</a>. Specifies the divider from PCLK to the PMU input clock. PCLK frequency is the same as the data rate (See <a href="#">D18F2x9C_x0002_0000_dct[3:0][PllMultDiv]</a> and <a href="#">D18F2x9C_x0002_0001_dct[3:0][PllMultDiv]</a>). This must be programmed so the PMU operates no faster than 533 MHz. Software should program this to the smallest divider which meets this condition for best training results. For example, if the data rate is 5Gb/s (PllMultDiv=3200h) then PMUClkDiv=divide by 10 (the PMU runs at 500 MHz). If for example, the data rate is 667Mb/s (PllMultDiv=0603h) then PMUClkDiv=divide by 2 (the PMU runs at 333 MHz). When training is complete and the PMU is in reset, it is recommended that BIOS program this to PMU CLK = CPU RefClk.</p> <table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>0000b</td><td>divide by 1</td></tr> <tr> <td>0001b</td><td>divide by 2</td></tr> <tr> <td>0010b</td><td>divide by 4</td></tr> <tr> <td>0011b</td><td>divide by 6</td></tr> <tr> <td>0100b</td><td>divide by 8</td></tr> <tr> <td>0101b</td><td>divide by 10</td></tr> <tr> <td>0111b</td><td>PMU CLK turned off</td></tr> <tr> <td>1111b-1000b</td><td>PMU CLK = CPU Refclk</td></tr> </table> | Bits | Description | 0000b | divide by 1 | 0001b | divide by 2 | 0010b | divide by 4 | 0011b | divide by 6 | 0100b | divide by 8 | 0101b | divide by 10 | 0111b | PMU CLK turned off | 1111b-1000b | PMU CLK = CPU Refclk |

#### D18F2x[B,0]9C\_x0005\_[5BFF:4000]\_dct[3:0] PMU IC SRAM

Cold reset: 0000\_0000h.

This is a word-addressable address space.

Software must write a pair of words into PMU SRAM, starting with an numbered index, in order for a write to be properly latched. E.g. writing to SRAM index 0 and then index 1 will result in two data words being written to SRAM; writing to index 0 only or index 1 only will result in no data being written to SRAM. If writing an even numbered word-sized block of SRAM then no additional writes are necessary. If writing with random access and software loses track of how many words were written, then it should assume the write was not latched and re-write utilizing a pair of accesses as stated above. It is not recommended to interrupt two consecutive writes with an intervening read operation.

| Bits  | Description                                                             |

**D18F2x9C\_x0005\_[0BFF:0000]\_dct[3:0] PMU SRAM Message Block**

Cold reset: 0000\_0000h.

This is a word-addressable address space. The lower 256 bytes of SRAM in the data portion of the address map is the SRAMMsgBlk. The remaining portion of the 6KB of SRAM is used by the system.

Software must write a pair of words into PMU SRAM, starting with an even numbered index, in order for a write to be properly latched. E.g. writing to SRAM index 0 and then index 1 will result in two data words being written to SRAM; writing to only an even index will result in no data written to SRAM; writing to only an odd index will result in arbitrary data written to the memory addressed by the corresponding even index (destroying the prior contents) but the odd index will be written with the intended data. If writing an even numbered word-sized block of SRAM aligned on an even index then no additional writes are necessary. If writing with random access and software loses track of how many words were written, then it should assume the write was not latched and re-write utilizing a pair of accesses as stated above. It is not recommended to interrupt two consecutive writes with an intervening read operation.

### D18F2x118 Memory Controller Configuration Low

Fields in this register (bits[17:0]) indicate priority of request types. Variable priority requests enter the memory controller as medium priority and are promoted to high priority if they have not been serviced in the time specified by MctVarPriCntLmt. This feature may be useful for isochronous IO traffic. If isochronous traffic is specified to be high priority, it may have an adverse effect on the bandwidth and performance of the devices associated with the other types of traffic. However, if isochronous traffic is specified as medium priority, the processor may not meet the isochronous bandwidth and latency requirements. The variable priority allows the memory controller to optimize DRAM transactions until isochronous traffic reaches a time threshold and must be serviced more quickly.

| Bits  | Description                                                                                                                                                                                                                            |                    |             |                    |

### D18F2x11C Memory Controller Configuration High

The two main functions of this register are to control write bursting and memory prefetching.

**Write bursting.** DctWrLimit and MctWrLimit specify how writes may be burst from the MCT into the DCT to improve DRAM efficiency. When the number of writes in the MCT reaches the value specified in MctWrLimit, then they are all burst to the DCTs at once. Prior to reaching the watermark, a limited number of writes can be passed to the DCTs (specified by DctWrLimit), tagged as low priority, for the DCTs to complete when otherwise idle. Rules regarding write bursting:

- Write bursting mode only applies to low-priority writes. Medium and high priority writes are not withheld from the DCTs for write bursting.
- If write bursting is enabled, writes stay in the MCQ until the threshold specified by MctWrLimit is reached.
- Once the threshold is reached, all writes in MCQ are converted to medium priority.
- Any write in MCQ that matches the address of a subsequent access is promoted to either medium priority or the priority of the subsequent access, whichever is higher.
- DctWrLimit only applies to low-priority writes.

**Memory prefetching.** The MCT prefetcher detects stride patterns in the stream of requests and then, for predictable stride patterns, generates prefetch requests. A stride pattern is a pattern of requests through system memory that are the same number of cachelines apart. The prefetcher supports strides of -4 to +4 cachelines, which can include alternating patterns (e.g. +1, +2, +1, +2), and can prefetch 1, 2, 3, 4, or 5 cachelines ahead, depending on the confidence. In addition, a fixed stride mode (non-alternating) may be used for IO requests which often have fixed stride patterns. This mode bypasses the stride predictor such that CPU-access stride predictions are not adversely affected by IO streams.

The MCT tracks several stride patterns simultaneously. Each of these has a confidence level associated with it that varies as follows:

- Each time a request is received that matches the stride pattern, the confidence level increases by one.
- Each time a request is received within +/- 4 cachelines of the last requested cacheline in the pattern that does not match the pattern, then the confidence level decreases by one.
- When the confidence level reaches the saturation point specified by PrefConfSat, then it no longer increments.

Each request that is not within +/- 4 cachelines of the last requested cacheline line of all the stride patterns tracked initiates a new stride pattern by displacing one of the existing least-recently-used stride patterns.

The memory prefetcher uses an adaptive prefetch scheme to adjust the prefetch distance based upon the buffer space available for prefetch request data. The adaptive scheme counts the total number of prefetch requests and the number of prefetch requests that cannot return data because of buffer availability. After every 16 prefetch requests, the prefetcher uses the following rules to adjust the prefetch distance:

- If the ratio of prefetch requests that cannot return data to total prefetch requests is greater than or equal to `D18F2x1B0[AdapPrefMissRatio]` then the prefetch distance is reduced by `D18F2x1B0[AdapPrefNegativeStep]`.
- If the ratio of prefetch requests that cannot return data to total prefetch requests is less than `D18F2x1B0[AdapPrefMissRatio]` then the prefetch distance is increased by `D18F2x1B0[AdapPrefPositiveStep]`.
- If the adjusted prefetch distance is greater than the prefetch distance defined for the current confidence level, the prefetch distance for the current confidence level is used.

The adaptive prefetch scheme supports fractional prefetch distances by alternating between two whole number prefetch distances. For example a prefetch distance of 1.25 causes a prefetch distance sequence of: 1, 1, 1, 2, 1, 1, 1, 2.

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                |      |             |      |    |           |                 |      |    |     |          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------|------|----|-----------|-----------------|------|----|-----|----------|
| 31        | <b>MctScrubEn: MCT scrub enable.</b> Read-write. Reset: 0. 1=Enables periodic flushing of prefetches and writes based on the DRAM scrub rate. This is used to ensure that prefetch and write data aging is not so long that soft errors accumulate and become uncorrectable. When enabled, each DRAM scrub event causes a single prefetch to be de-allocated (the oldest one) and all queued writes to be flushed to DRAM. |      |             |      |    |           |                 |      |    |     |          |
| 30        | <b>FlushWr: flush writes command.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. Setting this bit causes write bursting to be canceled and all outstanding writes to be flushed to DRAM. This bit is cleared when all writes are flushed to DRAM.                                                                                                                                                                  |      |             |      |    |           |                 |      |    |     |          |
| 29        | <b>FlushWrOnStpGnt: flush writes on stop-grant.</b> Read-write. Reset: 0. BIOS: <a href="#">~D18F2x1B4</a> [FlushWrOnS3StpGnt]. 1=Causes write bursting to be canceled and all outstanding writes to be flushed to DRAM when in the stop-grant state.                                                                                                                                                                      |      |             |      |    |           |                 |      |    |     |          |

### D18F2x1B0 Extended Memory Controller Configuration Low

The main function of this register is to control the memory prefetcher. See [D18F2x11C \[Memory Controller Configuration High\]](#) about the adaptive prefetch scheme.

**Table 180: BIOS Recommendations** for D18F2x1B[4:0]

| 26:24 | <b>TgtChipSelect: target chip select.</b> Read-write. Specifies the chip select.<br><div> <div>Bits</div> <div>Description</div> </div> 111b-000b CS<TgtChipSelect>                                                                                                                                                                                                                                                                                                                                                |
| 23:20 | <b>TgtBank: target bank [3:0].</b> Read-write. Specifies the bank address. If Ddr3Mode then TgtBank[3] is ignored.                                                                                                                                                                                                                                                                                                                                                                                                 |
| 19:16 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 15:10 | <b>TgtAddress[15:10]: target address [15:10].</b> Read-write. Specifies the upper column address bits [15:10]. Software must always program bit 10 and bit 12 equal to 0.                                                                                                                                                                                                                                                                                                                                          |
| 9:0   | <b>TgtAddress[9:0]: target address [9:0].</b> Read-write. Specifies the column address bits [9:0]. The address sequencing in a command series occurs as follows: TgtAddress[9:3] is incremented by one with wrap around. The increment occurs after each command if D18F2x250_dct[3:0][CmdType] = 00xb or if (D18F2x250_dct[3:0][CmdType] = 010b and D18F2x250_dct[3:0][CmdTgt] = 01b). The increment occurs after each command pair if (D18F2x250_dct[3:0][CmdType] = 010b and D18F2x250_dct[3:0][CmdTgt] = 00b). |

### D18F2x25C\_dct[3:0] DRAM Command 0

Reset: 0000\_0001h. See 2.9.3 [DCT Configuration Registers]. See 2.9.10 [Continuous Pattern Generation].

| 24:0         | <b>ErrCnt: error count.</b> Read; set-by-hardware; write-1-to-clear. Specifies a saturating counter indicating the number of DQ bit errors detected. Counts a maximum of 1 error per bit-lane per each bit-time. Status is accumulated until cleared by <a href="#">D18F2x250_dct[3:0][ResetAllErr]</a> . Errors can be masked on per-bit basis by programming <a href="#">D18F2x274_dct[3:0]</a> , <a href="#">D18F2x278_dct[3:0]</a> , and <a href="#">D18F2x27C_dct[3:0]</a> . <table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>0h</td><td>0 errors</td></tr> <tr> <td>1FF_FFFDh-1h</td><td>&lt;ErrCnt&gt; errors</td></tr> <tr> <td>1FF_FFFEh</td><td>1FF_FFFEh errors</td></tr> <tr> <td>1FF_FFFFh</td><td>1FF_FFFFh or more errors</td></tr> </table> | Bits | Description | 0h      | 0 errors         | 1FF_FFFDh-1h | <ErrCnt> errors | 1FF_FFFEh | 1FF_FFFEh errors | 1FF_FFFFh | 1FF_FFFFh or more errors |

| 0    | <b>EffArbDis: Efficient arbitration disable.</b> Read-write. Reset: 0. BIOS: 0. 0=The DCT optimizes the arbitration phases to improve performance under certain traffic conditions whenever the NCLK to MEMCLK ratio is less than 2:1. 1=The DCT arbitrates normally, at all NCLK:MEMCLK ratios. |

#### **D18F2x400\_dct[3:0] GMC to DCT Control 0**

Reset: 0000\_0000h. See [2.9.3 \[DCT Configuration Registers\]](#).

The GMC to DCT interface controls how DRAM bus resources are allocated and arbitrated between the MCT and the GMC. A token is the unit of available resource and is equivalent to a DCQ entry. A minimum count ensures a number of available DCQ entries. A token limit for MCT or GMC ensures resources are not all allocated to the GMC, or MCT respectively. Limits are configured bimodal: for normal GMC traffic and for when urgent (nominally display refresh) GMC traffic is occurring.

| 0    | <p><b>DataScrambleEn: data scramble enable.</b> Read-write; <a href="#">Same-for-all</a>. 1=Data scrambling enabled. Data stored in the DRAM will be scrambled. 0=Data scrambling disabled. This register must have the same value for all DCT's. This bit is valid for <a href="#">Ddr3Mode</a>. BIOS should set this bit prior to any memory write transactions to DRAM not generated by the DCT pattern generation logic.</p> <p>See <a href="#">D18F2x250_dct[3:0][CmdTestEnable]</a> for additional pattern generation requirements.</p> |

**D18F2xB64\_dct[3:0] Data Scramble Key**

---

Reset: 0000\_0000h. See [2.9.3 \[DCT Configuration Registers\]](#).

| Bits | Description                                                                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>DatScrambleKey:</b> data scramble key. Read-write; <a href="#">Same-for-all</a> . Specifies the key value used for data scrambling. This field is valid for <a href="#">Ddr3Mode</a> . |

### 3.12 Device 18h Function 3 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F3x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 141Dh. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F3x04 Status/Command

| Bits  | Description                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>Status.</b> Read-only. Reset: 0000h, except bit[20]. Bit[20] is set to indicate the existence of a PCI-defined capability block, if one exists. |
| 15:0  | <b>Command.</b> Read-only. Reset: 0000h.                                                                                                           |

#### D18F3x08 Class Code/Revision ID

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Reset: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only. Reset: 00h.                                                                     |

#### D18F3x0C Header Type

Reset: 0080\_0000h.

| Bits | Description                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> Read-only. These bits are fixed at their default values. The header type field indicates that there are multiple functions present in this device. |

#### D18F3x34 Capability Pointer

| Bits | Description                           |
|------|---------------------------------------|
| 31:8 | Reserved.                             |
| 7:0  | <b>CapPtr.</b> Read-only. Value: 00h. |

#### D18F3x40 MCA NB Control

Read-write. Reset: 0000\_0000h. [MSR0000\\_0410](#)[31:0] is an alias of [D18F3x40](#). See [MSR0000\\_0410](#)[31:0].

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 17    | <b>CpPktDatEn: completion packet error reporting enable.</b> Read-write. 1=Enables MCA reporting of completion packets with the EP bit set.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 16    | <b>NbIntProtEn: northbridge internal bus protocol error reporting enable.</b> Read-write. 1=Enables MCA reporting of protocol errors detected on the northbridge internal bus. When possible, this enable should be cleared before initiating a warm reset to avoid logging spurious errors due to RESET_L signal skew.                                                                                                                                                                                                                                                   |
| 15:13 | Unused.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 12    | <b>WDTRptEn: watchdog timer error reporting enable.</b> 1=Enables MCA reporting of watchdog timer errors. The watchdog timer checks for NB system accesses for which a response is expected but no response is received. See <a href="#">D18F3x44 [MCA NB Configuration]</a> for information regarding configuration of the watchdog timer duration. This bit does not affect operation of the watchdog timer in terms of its ability to complete an access that would otherwise cause a system hang. This bit only affects whether such errors are reported through MCA. |
| 11    | <b>AtomicRMWEn: atomic read-modify-write error reporting enable.</b> 1=Enables MCA reporting of atomic read-modify-write (RMW) commands received from an IO link. Atomic RMW commands are not supported. An atomic RMW command results in a link error response being generated back to the requesting IO device. The generation of the link error response is not affected by this bit.                                                                                                                                                                                  |
| 10    | Unused.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 9     | <b>TgtAbortEn: target abort error reporting enable.</b> 1=Enables MCA reporting of target aborts to a link. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of this bit.                                                                                                                                                                                                                                                                                                                                  |
| 8     | <b>MstrAbortEn: master abort error reporting enable.</b> 1=Enables MCA reporting of master aborts to a link. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of this bit.                                                                                                                                                                                                                                                                                                                                 |

| 1   | <b>UECCEn: uncorrectable ECC error reporting enable.</b> 1=Enables MCA reporting of DDR3 DRAM uncorrectable ECC errors which are detected in the NB. In some cases data may be forwarded to the core prior to checking ECC in which case the check takes place in one of the other error reporting banks. |
| 0   | <b>CECCEn: correctable ECC error reporting enable.</b> 1=Enables MCA reporting of DDR3 DRAM correctable ECC errors which are detected in the NB.                                                                                                                                                          |

### D18F3x44 MCA NB Configuration

See [D18F3x180 \[Extended NB MCA Configuration\]](#). It is expected that all fields of this register are programmed to the same value in all nodes, except for the fields used for link error injection: GenLinkSel, GenSubLinkSel, GenCrcErrByte1, GenCrcErrByte0.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Selects the sublink of a link selected by GenLinkSel to be used for CRC error injection through GenCrcErrByte0 and GenCrcErrByte1. When the link is ganged, GenSubLinkSel must be 00b. When the link is unganged, the following values indicate which sublink is selected:</p> <table> <thead> <tr> <th><u>Bits</u></th><th><u>Description</u></th></tr> </thead> <tbody> <tr> <td>00b</td><td>Sublink 0</td></tr> <tr> <td>01b</td><td>Sublink 1</td></tr> <tr> <td>10b</td><td>Reserved</td></tr> <tr> <td>11b</td><td>Reserved</td></tr> </tbody> </table>                               | <u>Bits</u> | <u>Description</u> | 00b | Sublink 0 | 01b | Sublink 1 | 10b | Reserved | 11b | Reserved |
| <u>Bits</u> | <u>Description</u>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                    |     |           |     |           |     |          |     |          |

#### D18F3x58 Scrub Rate Control

This register specifies the ECC sequential scrubbing rate for lines of memory and cache. See 2.8.3 [[Memory Scrubbers](#)]. Scrub rates are a platform consideration. See 2.15.1.8 [[Scrub Rate Considerations](#)].

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |             |      |             |     |                              |     |         |     |                    |     |         |     |                    |     |         |     |                     |     |          |     |                     |     |          |     |        |     |       |     |         |     |       |     |         |         |          |     |         |     |          |     |         |  |  |     |         |  |  |     |         |  |  |     |         |  |  |     |          |  |  |     |          |  |  |     |          |  |  |

### D18F3x5C DRAM Scrub Address Low

In addition to sequential DRAM scrubbing, the DRAM scrubber has a redirect mode for scrubbing DRAM locations accessed during normal operation. This is enabled by setting [D18F3x5C](#)[ScrubReDirEn]. When a DRAM read is generated by any agent other than the DRAM scrubber, correctable ECC errors are corrected as the data is passed to the requestor, but the data in DRAM is not corrected if redirect scrubbing mode is disabled. In scrubber redirect mode, correctable errors detected during normal DRAM read accesses redirect the scrubber to the location of the error. After the scrubber corrects the location in DRAM, it resumes scrubbing from where it left off. DRAM scrub address registers are not modified by the redirect scrubbing mode. Sequential scrubbing and scrubber redirection can be enabled independently or together. ECC errors detected by the scrubber are logged in the MCA registers (See [D18F3x40](#) [MCA NB Control]).

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 31:6 | <b>ScrubAddr[31:6]: DRAM scrubber address bits[31:6].</b> Read-write; updated-by-hardware. ScrubAddr[47:6] = {D18F3x60[ScrubAddr[47:32]], ScrubAddr[31:6]}. Reset: 0. ScrubAddr points to a DRAM cacheline in physical address space. BIOS should initialize the scrubber address register to the base address of the node specified by D18F1x[17C:140,7C:40] [DRAM Base/Limit] prior to enabling sequential scrubbing through D18F3x58[DramScrub]. When sequential scrubbing is enabled: it starts at the address that the scrubber address registers are initialized to; it increments through address space and updates the scrubber address registers as it does so; when the scrubber reaches the DRAM limit address specified by D18F1x[17C:140,7C:40], it wraps around to the base address. Reads of the scrubber address registers provide the next cacheline to be scrubbed. |

| 0    | <b>ScrubReDirEn: DRAM scrubber redirect enable.</b> Read-write. Reset: 0. If a correctable error is discovered from a non-scrubber DRAM read, then the data is corrected before it is returned to the requestor; however, the DRAM location may be left in a corrupted state (until the next time the scrubber address counts up to that location, if sequential scrubbing is enabled through D18F3x58[DramScrub]). 1=Enables the scrubber to immediately scrub any address in which a correctable error is discovered. This bit and sequential scrubbing can be enabled independently or together; if both are enabled, the scrubber jumps from the scrubber address to where the correctable error was discovered, scrubs that location, and then jumps back to where it left off; the scrubber address register is not affected during scrubber redirection.                       |

### D18F3x60 DRAM Scrub Address High

| Bits  | Description                                                                                           |

### D18F3x6C Data Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- To ensure deadlock free operation the following minimum buffer allocations are required:
  - [D18F3x6C\[UpRspDBC\]](#)  $\geq 1$ .
  - [D18F3x6C\[DnReqDBC\]](#)  $\geq 1$ .
  - [D18F3x6C\[UpReqDBC\]](#)  $\geq 1$ .
  - [D18F3x6C\[DnRspDBC\]](#)  $\geq 1$ .
- If [D18F0x\[E4,C4,A4,84\]\[IsocEn\]](#)=1: [IsocRspDBC](#)  $\geq 1$ .
- The total number of data buffers allocated in this register and [D18F3x7C](#) must satisfy the following equation:
 
$$\begin{aligned} & \text{D18F3x6C[UpReqDBC]} + \text{D18F3x6C[UpRspDBC]} + \text{D18F3x6C[DnReqDBC]} + \\ & \text{D18F3x6C[DnRspDBC]} + \text{D18F3x6C[IsocRspDBC]} + (\text{IF } (\text{D18F3x7C[Sri2XbarFreeRspDBC]}==0) \\ & \text{THEN } (\text{D18F3x7C[Sri2XbarFreeXreqDBC]}*2) \text{ ELSE } \text{D18F3x7C[Sri2XbarFreeXreqDBC]} \text{ ENDIF}) + \\ & \text{D18F3x7C[Sri2XbarFreeRspDBC]} \leq 16. \end{aligned}$$

### D18F3x70 SRI to XBAR Command Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- To ensure deadlock free operation the following minimum buffer allocations are required:
  - [D18F3x70\[UpRspCBC\]](#)  $\geq 1$ .
  - [D18F3x70\[UpPreqCBC\]](#)  $\geq 1$ .
  - [D18F3x70\[DnPreqCBC\]](#)  $\geq 1$ .
  - [D18F3x70\[UpReqCBC\]](#)  $\geq 1$ .
  - [D18F3x70\[DnReqCBC\]](#)  $\geq 1$ .
  - [D18F3x70\[DnRspCBC\]](#)  $\geq 1$ .
- If any of the [D18F0x\[E4,C4,A4,84\]\[IsocEn\]](#) bits are set:

IsocReqCBC >= 1                      IsocRspCBC >= 1

- If **D18F0x[E4,C4,A4,84]**[IsocEn]=1 and isochronous posted requests may be generated by the system:

IsocPreqCBC >= 1

- The total number of SRI to XBAR commandbuffers allocated in this register and **D18F3x7C** must satisfy the following equation:

$$\begin{aligned} & \bullet \text{D18F3x70[IsocRspCBC]} + \text{D18F3x70[IsocPreqCBC]} + \text{D18F3x70[IsocReqCBC]} + \\ & \text{D18F3x70[UpRspCBC]} + \text{D18F3x70[DnPreqCBC]} + \text{D18F3x70[UpPreqCBC]} + \\ & \text{D18F3x70[DnReqCBC]} + \text{D18F3x70[DnRspCBC]} + \text{D18F3x70[UpReqCBC]} + \\ & \text{D18F3x7C[Sri2XbarFreeRspCBC]} + \text{D18F3x7C[Sri2XbarFreeXreqCBC]} \leq 48. \end{aligned}$$

| Bits  | Description                                                                                           |

### D18F3x74 XBAR to SRI Command Buffer Count

Cold reset: 0007\_1111h. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use **D18F0x6C**[RlsLnkFullTokCntImm] for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

**Table 184: Buffer Definitions**

| Term           | Definition                                                                |
|----------------|---------------------------------------------------------------------------|
| <b>SpqSize</b> | Probe command queue size.<br>SpqSize = 20.                                |
| <b>SrqSize</b> | SRQ (XBAR command and probe response to SRI) queue size.<br>SrqSize = 52. |

**Table 184: Buffer Definitions**

| Term            | Definition                                                 |
|-----------------|------------------------------------------------------------|
| <b>PrbRsp</b>   | SRQ entries hard allocated to probe responses. PrbRsp = 4. |
| <b>MpbcSize</b> | MPB command buffer size.<br>MpbcSize = 48.                 |
| <b>McqSize</b>  | MCT command queue size.<br>McqSize = 72.                   |

- To ensure deadlock free operation the following minimum buffer allocations are required:
  - $D18F3x74[ProbeCBC] \geq 2$ .
  - $D18F3x74[UpReqCBC] \geq 1$ .
  - $D18F3x74[UpPreqCBC] \geq 1$ .
  - $(IsocReqCBC + IsocPreqCBC + DRReqCBC) \leq 31$ .
  - $(IsocReqCBC + IsocPreqCBC + DRReqCBC) \leq (McqSize - 16)$ .
- If any of  $D18F0x[E4,C4,A4,84][IsocEn]$  bits are set, then  $IsocReqCBC \geq 1$ .
- If any of the  $D18F0x[E4,C4,A4,84][IsocEn]$  bits are set and isochronous posted requests may be generated by the system:  
 $IsocPreqCBC \geq 1$
- The total number of XBAR to SRI commandbuffers allocated in this register and  $D18F3x7C$  must satisfy the following equation:
  - $D18F3x74[UpReqCBC] + D18F3x74[UpPreqCBC] + D18F3x74[DnReqCBC] + D18F3x74[DnPreqCBC] + D18F3x74[IsocReqCBC] + D18F3x74[IsocPreqCBC] + D18F3x74[DRReqCBC] + D18F3x7C[Xbar2SriFreeListCBC] + (D18F3x1A0[CpuCmdBufCnt] * NumOfCompUnits) + D18F3x1A0[CpuToNbFreeBufCnt] + PrbRsp \leq SrqSize$
- The total number of SPQ (probe command) buffers allocated must satisfy the following equation:
  - $(D18F3x17C[SPQPrbFreeCBC] + D18F3x74[ProbeCBC]) \leq SpqSize$ .

| Bits  | Description                                                                                                                                                                                                                                                                     |      |             |    |           |       |                    |       |           |

### D18F3x78 MCT to XBAR Buffer Count

Cold Reset: 0024\_0519h. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- To ensure deadlock free operation the following minimum buffer allocations are required:  
 $\text{ProbeCBC} \geq 1$                        $\text{RspCBC} \geq 1$                        $\text{RspDBC} \geq 2$   
 $\text{RspDBC} \geq \text{D18F2x11C}[\text{MctPrefReqLimit}] + 2$
- The total number of command buffers allocated in this register must satisfy the following equation:  
 $(\text{D18F3x78}[\text{ProbeCBC}] + \text{D18F3x78}[\text{RspCBC}]) \leq \text{MpbcsSize}.$

### D18F3x[84:80] ACPI Power State Control

This block consists of eight identical 8-bit registers, one for each System Management Action Field (SMAF) code associated with STPCLK assertion commands from the link. Refer to the descriptions below for the associated ACPI state and system management actions for each of the 8 SMAF codes. The SmafAct fields specify the system management actions taken when the corresponding SMAF code is received. For instance, a SMAF code of 5 results in the power management actions specified by SmafAct5. Some ACPI states and associated SMAF codes may not be supported in certain conditions. See [2.5 \[Power Management\]](#) for which states are supported.

When a link STPCLK assertion command is received by the processor, the power management commands specified by the register with the corresponding SMAF code are invoked. When the STPCLK deassertion command is received by the processor, the processor returns into the operational state.

In multi-node systems, these registers should be programmed identically in all nodes.

**Table 185: SMAF Action Definition**

| Register                         | SmafAct  | ACPI state         | Description                                                                                                                                                                                         |
|----------------------------------|----------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">D18F3x84</a> [31:24] | SmafAct7 | C1                 | Initiated when a Halt instruction is executed by processor. This does not involve the interaction with the SMC, therefore the SMC is required to never send STPCLK assertion commands with SMAF=7h. |
| <a href="#">D18F3x84</a> [23:16] | SmafAct6 | S4/S5              | Initiated by a processor access to the ACPI-defined PM1_CNTa register.                                                                                                                              |
| <a href="#">D18F3x84</a> [15:8]  | SmafAct5 | Throttling         | Occurs based upon SMC hardware-initiated throttling. AMD recommends using PROCHOT_L for thermal throttling and not implementing stop clock based throttling.                                        |
| <a href="#">D18F3x84</a> [7:0]   | SmafAct4 | S3                 | Initiated by a processor access to the ACPI-defined PM1_CNTa register.                                                                                                                              |
| <a href="#">D18F3x80</a> [31:24] | SmafAct3 | S1                 | Initiated by a processor access to the ACPI-defined PM1_CNTa register.                                                                                                                              |
| <a href="#">D18F3x80</a> [23:16] | SmafAct2 | -                  |                                                                                                                                                                                                     |
| <a href="#">D18F3x80</a> [15:8]  | SmafAct1 | C1E, or Link init. | Initiated by an access to the ACPI-defined P_LVL3 register.                                                                                                                                         |
| <a href="#">D18F3x80</a> [7:0]   | SmafAct0 | C2                 | Initiated by a processor access to the ACPI-defined P_LVL2 register.                                                                                                                                |

#### **D18F3x80 ACPI Power State Control Low**

|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>CofVidProg: COF and VID of P-states programmed.</b> Read-only. Reset: Product-specific. 1=Out of cold reset, the VID, FID, and DID values of the P-state registers specified by <a href="#">MSRC001_0071</a> [StartupPstate] and <a href="#">D18F5x174</a> [StartupNbPstate] have been applied to the processor. 0=Out of cold reset, the boot VID is applied to all processor power planes, the NB clock plane is set to 800 MHz (with a FID of 00h=800 MHz and a DID of 0b) and core CPU clock planes are set to 800 MHz (with a FID of 00h=1.6 GHz and a DID of 1h). Registers containing P-state information such as FID, DID, and VID values are valid out of cold reset independent of the state of <a href="#">D18F3xA0</a> [CofVidProg]. BIOS must transition the processor to a valid P-state out of cold reset when <a href="#">D18F3xA0</a> [CofVidProg]=0. See 2.5.3.1.6 [BIOS Requirements for Core P-state Initialization and Transitions]. |

| 7           | <b>PsiVidEn: PSI_L VID enable.</b> Read-write. Reset: 0. BIOS: 2.5.1.3.1.1. This bit specifies how PSI_L is controlled. This signal may be used by the voltage regulator to improve efficiency while in reduced power states. 1=Control over the PSI_L signal is as specified by the PsiVid field of this register. 0=PSI_L is always high. See 2.5.1.3.1 [PSIx_L Bit].                                                                                                                                                                                                                                                 |             |                    |             |                    |      |      |      |      |      |      |      |       |      |      |      |          |      |      |      |          |
| 6:0         | <b>PsiVid[6:0]: PSI_L VID threshold.</b> Read-write. Reset: 0. BIOS: 2.5.1.3.1.1. PsiVid[7:0] = {PsiVid[7], PsiVid[6:0]}. When enabled by PsiVidEn, PsiVid[7:0] specifies the threshold value of the VID code generated by the processor, which in turn determines the state of PSI0_L. When the VID code generated by the processor is less than PsiVid[7:0] (i.e., the VID code is specifying a higher voltage level than the PsiVid-specified voltage level), then PSI0_L is high; when the VID code is greater than or equal to PsiVid[7:0], PSI0_L is driven low. See 2.5.1.3.1 [PSIx_L Bit].                      |             |                    |             |                    |      |      |      |      |      |      |      |       |      |      |      |          |      |      |      |          |

### D18F3xA4 Reported Temperature Control

The slew rate controls in this register are used to filter processor temperature measurements. Separate controls are provided for a measured temperature that is higher or lower than Tctl. The per-step timer counts as long as the measured temperature stays either above or below Tctl. Each time the measured temperature changes to the other side of Tctl, the step timer resets, and Tctl is not changed. If, for example, step times are enabled in both directions, Tctl=62.625, and the measured temperature keeps jumping quickly between 62.5 and 63.0, then (assuming the step times are long enough) Tctl would not change. However, once the measured temperature settles on one side of Tctl, Tctl can step toward the measured temperature. If the difference of measured temperature minus Tctl is greater than the value set by MaxTmpDiffUp, then Tctl is set equal to the measured temperature. See 2.10 [Thermal Functions].

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                     |                 |             |                                                                                      |     |           |      |           |         |                                                                                                               |   |                     |      |   |         |      |   |   |      |   |       |           |   |                |      |   |         |

| 28:0  | Reserved.                                                                                                                                                                                                                                                                        |

### D18F3xB8 NB Array Address

Reset: xxxx\_xxxxh. [D18F3xB8 \[NB Array Address\]](#) and [D18F3xBC \[NB Array Data Port\]](#) provide a mechanism to inject errors into DRAM and data read from internal NB arrays.

[D18F3xB8](#) should first be written with the target array and address within the array. Read and write accesses to [D18F3xBC](#) then access the target address within the target array.

### D18F3xBC NB Array Data Port

See [D18F3xB8](#) for register access information. Address: [D18F3xB8\[ArraySelect\]](#).

| Bits | Description   |
|------|---------------|
| 31:0 | <b>Data</b> . |

### D18F3xBC\_x8 DRAM ECC

This register controls injection of errors in writes to DRAM. See [2.15.3.1 \[DRAM Error Injection\]](#).

| Bits  | Description |
|-------|-------------|
| 31:29 | Reserved.   |

| 28:20 | <p><b>ErrInjEn: enable error injection to word.</b> Read-write. Reset: 0. Each bit in this field corresponds to a 16-bit DRAM word and enables injecting errors in that word.</p> <table> <tr> <th>Bit</th><th>Description</th></tr> <tr> <td>[0]</td><td>Data[15:0]</td></tr> <tr> <td>[1]</td><td>Data[31:16]</td></tr> <tr> <td>[2]</td><td>Data[47:32]</td></tr> <tr> <td>[3]</td><td>Data[63:48]</td></tr> <tr> <td>[4]</td><td>Data[79:64]</td></tr> <tr> <td>[5]</td><td>Data[95:80]</td></tr> <tr> <td>[6]</td><td>Data[111:96]</td></tr> <tr> <td>[7]</td><td>Data[127:112]</td></tr> <tr> <td>[8]</td><td>ECC[15:0]</td></tr> </table> | Bit | Description | [0] | Data[15:0] | [1] | Data[31:16] | [2] | Data[47:32] | [3] | Data[63:48] | [4] | Data[79:64] | [5] | Data[95:80] | [6] | Data[111:96] | [7] | Data[127:112] | [8] | ECC[15:0] |

| 18    | <b>DramErrEn.</b> Read-write. Reset: 0. 1=Errors are continually injected on DRAM writes. The error injection takes place only on DRAM write accesses and should be initiated by a non-cacheable store. Errors continue to be injected on writes until this bit is cleared to a 0 by software.                                                                                                                                                                                                                                                                                                                                                   |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |
| 17    | <b>EccWrReq.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. 1=Error is injected on DRAM write at the bits enabled by ErrInjEn and EccVector. A single error injection takes place on the next DRAM write access and should be initiated by a non-cacheable store. This bit is cleared by hardware after the write.                                                                                                                                                                                                                                                                                                                       |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |
| 16    | <b>EccRdReq.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. 1=Indicates a DRAM ECC read is requested. The read takes place on the next DRAM read access and should be initiated by a non-cacheable load. The ECC bits read from DRAM are stored in EccVector. This bit is cleared by hardware after the read.                                                                                                                                                                                                                                                                                                                            |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |
| 15:0  | <b>EccVector: error injection vector.</b> Read-write. Reset: x. When used in conjunction with EccWrReq, each bit of EccVector enables injecting errors to the corresponding bit within each word enabled by ErrInjEn. When used in conjunction with EccRdReq, EccVector holds the contents of the DRAM ECC bits after the read.                                                                                                                                                                                                                                                                                                                  |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |

| 27:24       | <p><b>PowerStepUp.</b> Read-write. Cold reset: 0000b. Specifies the rate at which blocks of compute unit and NB logic are gated on while the processor transitions from a quiescent state to an active state as part of a power management state transition. There are about 15 steps in this transition for each compute unit and about 5 steps for the NB for the PowerStepDown and PowerStepUp transitions. So the total transition time for a single compute unit is about 15 times the time specified by PowerStepDown and PowerStepUp and the transition time for the NB is about 5 times the time specified by PowerStepDown and PowerStepUp. Use of longer transition times may help reduce voltage transients associated with power state transitions. The bits for PowerStepUp and PowerStepDown are encoded as follows:</p> <table><tr><td><u>Bits</u></td><td><u>Description</u></td><td><u>Bits</u></td><td><u>Description</u></td></tr><tr><td>0000b</td><td>Reserved.</td><td>1000b</td><td>50 ns</td></tr><tr><td>0001b</td><td>Reserved.</td><td>1001b</td><td>Reserved.</td></tr><tr><td>0010b</td><td>Reserved.</td><td>1010b</td><td>Reserved.</td></tr><tr><td>0011b</td><td>100 ns</td><td>1011b</td><td>Reserved.</td></tr><tr><td>0100b</td><td>90 ns</td><td>1100b</td><td>Reserved.</td></tr><tr><td>0101b</td><td>80 ns</td><td>1101b</td><td>Reserved.</td></tr><tr><td>0110b</td><td>70 ns</td><td>1110b</td><td>Reserved.</td></tr><tr><td>0111b</td><td>60 ns</td><td>1111b</td><td>Reserved.</td></tr></table> <ul style="list-style-type: none"><li>• If PowerStepDown or PowerStepUp are programmed to greater than 50 ns, then the value applied to the NB is clipped to 50 ns. The compute unit steps are not clipped.</li><li>• BIOS: 1000b.</li></ul> | <u>Bits</u> | <u>Description</u> | <u>Bits</u> | <u>Description</u> | 0000b | Reserved.   | 1000b | 50 ns        | 0001b | Reserved.   | 1001b | Reserved. | 0010b | Reserved.   | 1010b | Reserved. | 0011b | 100 ns      | 1011b | Reserved. | 0100b | 90 ns | 1100b | Reserved. | 0101b | 80 ns | 1101b | Reserved. | 0110b | 70 ns | 1110b | Reserved. | 0111b | 60 ns | 1111b | Reserved. |

| 23:20       | <p><b>PowerStepDown.</b> Read-write. Cold reset: 0000b. BIOS: 1000b. This specifies the rate at which blocks of compute unit and NB logic are gated off while the processor transitions from an active state to a quiescent state as part of a power management state transition. Valid values are the same as those for PowerStepUp.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                    |             |                    |       |             |       |              |       |             |       |           |       |             |       |           |       |             |       |           |       |       |       |           |       |       |       |           |       |       |       |           |       |       |       |           |

| 11:8 | <b>ClkRampHystSel: clock ramp hysteresis select.</b> Read-write. Cold reset: 0h. BIOS: Fh. When the core(s) are in the stop-grant or halt state and a probe request is received, the core clock may need to be brought up to service the probe.<br><ul style="list-style-type: none"> <li>• If (<a href="#">D18F4x128</a>[CoreCstateMode] ? (<a href="#">D18F3x80/D18F3x84</a>[CpuPrbEn]==0) : (<a href="#">D18F4x118/D18F4x11C</a>[CpuPrbEn]==0)) then this field specifies how long the core clock is left up to service additional probes before being brought back down. Each time a probe request is received, the hysteresis timer is reset such that the period of time specified by this field must expire with no probe request before the core clock is brought back down. The hysteresis time is encoded as (the time base specified by <a href="#">D18F3xD4</a>[ClkRampHystCtl]) * (1 + ClkRampHystSel).</li> <li>• If (<a href="#">D18F4x128</a>[CoreCstateMode] ? (<a href="#">D18F3x80/D18F3x84</a>[CpuPrbEn]==1) : (<a href="#">D18F4x118/D18F4x11C</a>[CpuPrbEn]==1)) then this field specifies a fixed amount of time to allow for probes to be serviced after completing the transition of each core. If, for example, two cores enter stop-grant or halt at the same time, then (1) the first core would complete the transition to the low power state, (2) probe traffic would be serviced for the time specified by this field, (3) the second core would complete the transition to the low power state, and (4) probe traffic would be serviced for the time specified by this field (and afterwards, until the next power state transition). For this purpose, values range from 0h=40 ns to Fh=640 ns, encoded as 40 ns * (1 + ClkRampHystSel).</li> </ul> |

| 5:0  | <b>MaxSwPstateCpuCof: maximum software P-state core COF.</b> Read-only. Cold reset: Product-specific. Specifies the maximum CPU COF supported by the processor in a software P-state. The maximum frequency is 100 MHz * MaxSwPstateCpuCof, if MaxSwPstateCpuCof is greater than zero; if MaxSwPstateCpuCof = 00h, then there is no frequency limit. Any attempt to change a software P-state CPU COF to a frequency greater than specified by this field is ignored. See <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 14:12       | <p><b>NbsynPtrAdj: NB/core synchronization FIFO pointer adjust.</b> Read-write. Cold reset: 000b. BIOS: IF (<a href="#">D18F5x260</a>[ClkStretchEn] &amp;&amp; <a href="#">D18F5x260</a>[ClkStretchPercent]==1) THEN 011b ELSIF (<a href="#">D18F5x260</a>[ClkStretchEn] &amp;&amp; <a href="#">D18F5x260</a>[ClkStretchPercent]==2) THEN 011b ELSE 101b. Changes to this field take effect after any of the following events:</p> <ul style="list-style-type: none"> <li>• Warm reset.</li> <li>• At least one core on all compute units perform a P-state transition.</li> <li>• An NB P-state transition.</li> </ul> <p>There is a synchronization FIFO between the NB clock domain and core clock domains. At cold reset, the read pointer and write pointer for each of these FIFOs is positioned conservatively, such that FIFO latency may be greater than is necessary.</p> <p>NbsynPtrAdj and NbsynPtrAdjLo may be used to position the read pointer and write pointer of each FIFO closer to each other such that latency is reduced. Each increment of NbsynPtrAdj and NbsynPtrAdjLo represents one clock cycle of whichever is the slower clock (longer period) between the NB clock and the core clock. NbsynPtrAdj is used when the core P-state is less than or equal to NbsynPtrAdjPstate, otherwise NbsynPtrAdjLo is used.</p> <p>Values less than the recommended value are allowed; values greater than the recommended value are illegal.</p> <table> <tr> <th><u>Bits</u></th><th><u>Description</u></th></tr> <tr> <td>6h-0h</td><td>Position the read pointer &lt;NbsynPtrAdj, NbsynPtrAdjLo&gt; clock cycles closer to the write pointer.</td></tr> <tr> <td>7h</td><td>Reserved</td></tr> </table> | <u>Bits</u> | <u>Description</u> | 6h-0h | Position the read pointer <NbsynPtrAdj, NbsynPtrAdjLo> clock cycles closer to the write pointer. | 7h   | Reserved    |      |             |      |             |      |              |      |          |      |          |      |                 |

### D18F3x140 SRI to XCS Token Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

[D18F3x140](#), [D18F3x144](#), and [D18F3x1\[54:48\]](#) specify the number of XCS (XBAR command scheduler) entries assigned to each virtual channel within each source port. See [2.8 \[Northbridge \(NB\)\]](#).

The default totals are:

Buffer allocation rules:

- The totals of SRI, MCT and the links must not exceed the number of XCS entries.  $XcsSize = 52$ .
  - $SUM(D18F3x140[UpReqTok, UpPreqTok, UpRspTok, DnReqTok, DnPreqTok, DnRspTok, IsocReqTok, IsocPreqTok, IsocRspTok, FreeTok]) + SUM(D18F3x144[ProbeTok, RspTok]) + SUM(D18F3x148[ReqTok0, PReqTok0, RspTok0, ProbeTok0, \{FreeTok[3:2], FreeTok[1:0]\}, IsocReqTok0, IsocPreqTok0, IsocRspTok0, ReqTok1, PReqTok1, RspTok1, ProbeTok1, IsocReqTok1, IsocPreqTok1, IsocRspTok1]) + SUM(D18F3x14C[ReqTok0, PReqTok0, RspTok0, ProbeTok0, \{FreeTok[3:2], FreeTok[1:0]\}, IsocReqTok0, IsocPreqTok0, IsocRspTok0, ReqTok1, PReqTok1, RspTok1, ProbeTok1, IsocReqTok1, IsocPreqTok1, IsocRspTok1]) \leq XcsSize$ . See [D18F3x1\[54:48\]](#).

The defaults for [D18F3x140](#) and [D18F3x1\[54:48\]](#) do not allocate any tokens in the isochronous channel. If isochronous flow control mode (IFCM) is enabled ([D18F0x\[E4,C4,A4,84\]\[IsocEn\]](#)), then the XCS token counts must be changed.

- If IFCM is enabled, then [D18F3x140\[IsocReqTok, IsocRspTok\]](#) must each be non-zero. If isochronous posted requests may be generated in the system, then [D18F3x140\[IsocPreqTok\]](#) must also be non-zero.
- If an IOMMU is present, [D18F3x1\[54:48\]\[IsocReqTok\]](#) must be non-zero.

### D18F3x17C Extended Freelist Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use D18F0x6C[RlsLnkFullTokCntImm] for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

| Bits | Description                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------|
| 31:4 | Reserved.                                                                                                       |

## D18F3x1A0 Core Interface Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use D18F0x6C[RlsLnkFullTokCntImm] for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- The following buffer allocations rules must be satisfied:
  - CpuCmdBufCnt >= 2.

### D18F3x1CC IBS Control

Reset: 0000\_0000h. [MSRC001\\_103A](#) is an alias of [D18F3x1CC](#). [D18F3x1CC](#) is programmed by BIOS; The OS reads the LVT offset from [MSRC001\\_103A](#).

| 3:0   | <b>DctPwrGateEn.</b> Read-write. Cold reset: 0h. BIOS: 6h. 1=Enable static DCT power gating. 0=Disable static DCT power gating. [0]=DCT 0; ...; [3]=DCT 3. There are two power islands in the DCT, one for DCT 0 and 3, and another for DCT 1 and 2. An island is only power gated if power gating is enabled for all DCTs on the power island. An island is physically power gated when the northbridge enters its NB C-state, and remain so if configured properly with DctPwrGateEn. For any given DCT, DctClkGateEn is required to be set prior to or in parallel with DctPwrGateEn being set. |      |             |     |          |     |            |     |             |     |             |

| 4:2     | <b>HaltCstateIndex.</b> Read-write. BIOS: 0. Specifies the IO-based C-state that is invoked by a HLT instruction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |             |     |                                                                  |         |                                                                            |     |                                           |     |          |
| 1       | <b>CoreCstatePolicy.</b> Read-write. BIOS: 0. Specifies how the processor arbitrates voltage and frequency when different non-C0 C-state requests are received on each core in a compute unit. 0=Transition both cores to the shallower C-state request. 1=Transition both cores to the deeper C-state request. For instance, if core 0 gets a request to go to C2 and core 1 gets a request to go to C1, hardware looks at the setting of CoreCstatePolicy. If CoreCstatePolicy is programmed to 0, the processor sends both cores to C1. If CoreCstatePolicy is programmed to 1, the processor sends both cores to C2. BIOS should program this field to the same value in all nodes of a multi-node processor. See also <a href="#">2.5.2.1 [Dependencies Between Cores]</a> . |      |             |     |                                                                  |         |                                                                            |     |                                           |     |          |
| 0       | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |             |     |                                                                  |         |                                                                            |     |                                           |     |          |

| 11:9  | <b>CstateCnt: C-state count.</b> IF <a href="#">D18F4x15C</a> [BoostLock] THEN Read-only. ELSE Read-write. ENDIF.<br>Reset: Product-specific. Specifies the number of cores or compute units (see CstateCores) that must be in CC6 before a transition can occur to a boosted P-state that is higher performance than the P-state specified by CstateBoost. A value of 0 disables access to P-states above CstateBoost.                                                                                                                                                                                                                                                                                                                                                                                    |     |             |    |                                                  |    |                                          |
| 8:6   | <b>CstateBoost.</b> Read-write. Reset: Product-specific. Specifies the P-state which requires the number of cores or compute units (see CstateCores) specified in CstateCnt to be in CC6 before a transition to a higher performance (lower numbered) boosted P-state is allowed. CstateBoost must be less than or equal to <a href="#">D18F4x15C</a> [NumBoostStates] otherwise undefined behavior results. If <a href="#">D18F4x15C</a> [BoostLock]=1, CstateBoost can only be written with values that are greater than or equal to the reset value. Attempts to write values less than the reset value are ignored. A value of 0 indicates that the C-state boost feature is not supported. This field uses hardware P-state numbering. See <a href="#">2.5.3.1.1.2 [Hardware P-state Numbering]</a> . |     |             |    |                                                  |    |                                          |

| 30:28 | <b>TdpLimitPstate</b> . Read-write. Reset: 0. Specifies the highest performance P-state that has a power consumption less than or equal to the TDP limit. This field is programmed by BIOS and uses software P-state numbering. See <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> .                                                                                                                                                                                                                                                                                       |
| 27:12 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 11:0  | <b>NodeTdpLimit</b> . Read-write; <a href="#">Same-for-all</a> . Reset: Product-specific. Specifies the maximum allowed sum of TDPs from all cores on a node. If the consumed power exceeds the NodeTdpLimit, a P-state limit is applied to all cores on the processor to reduce the powerconsumption so that it remains within the TDP limit. If <a href="#">D18F4x15C[BoostLock]</a> =1, NodeTdpLimit can only be written with values that are less than or equal to the reset value. Attempts to write an invalid value are ignored. See <a href="#">2.5.9.2 [TDP Limiting]</a> . |

### 3.14 Device 18h Function 5 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F5x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 141Fh. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F5x04 Status/Command

| Bits  | Description                              |
|-------|------------------------------------------|
| 31:16 | <b>Status.</b> Read-only. Value: 0000h.  |
| 15:0  | <b>Command.</b> Read-only. Value: 0000h. |

#### D18F5x08 Class Code/Revision ID

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Value: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only. Value: 00h.                                                                     |

#### D18F5x0C Header Type

| Bits | Description                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> Read-only. Reset: 0080_0000h. These bits are fixed at their default values. The header type field indicates that there are not multiple functions present in this device. |

#### D18F5x34 Capabilities Pointer

| Bits | Description                                                 |
|------|-------------------------------------------------------------|
| 31:8 | Reserved.                                                   |
| 7:0  | <b>CapPtr:</b> capabilities pointer. Read-only. Value: 00h. |

#### D18F5x[70,60,50,40] Northbridge Performance Event Select Low

| Bits | Description                                                                   |

**D18F5x80 Compute Unit Status 1**

See [2.4.4 \[Processor Cores and Downcoring\]](#).

Software associates core ID to the cores of the compute units according to the following table. All combinations not listed are reserved.

**Table 187: D18F5x80[Enabled, DualCore] Definition**

| Enabled | DualCore | Definition                                                                |
|---------|----------|---------------------------------------------------------------------------|
| 1h      | 1h       | 1 compute unit is enabled; both cores of the compute unit are enabled.    |
| 3h      | 3h       | 2 compute units are enabled; both cores of each compute unit are enabled. |

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |     |             |     |                |     |                |       |          |

| 3:0  | <b>RunAvgRange: running average range.</b> Read-write; <a href="#">Same-for-all</a> . Reset: 0. BIOS: 2h. Specifies the interval over which the processor averages power consumption estimates from the cores for boosting. Time interval = $2^{(\text{RunAvgRange} + 1)} \times \text{FreeRunSampleTimer}$ rate. A value of 0 disables the TDP running average accumulator capture function. See <a href="#">2.5.9 [Application Power Management (APM)]</a> . |

### D18F5xE8 TDP Limit 3

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:29 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                             |
| 28:16 | <b>ApmTdpLimit.</b> Read-only; updated-by-hardware. Value: <a href="#">D18F4x250[NodeTdpLimit]</a> . If the consumed node power exceeds the ApmTdpLimit on an single node processor or the ApmTdpLimit/2 on a multi-node processor, a P-state limit is applied to all cores on all nodes to reduce the power consumption to remain within the TDP limit. See <a href="#">2.5.9.2 [TDP Limiting]</a> . |
| 15:10 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                             |
| 9:0   | <b>Tdp2Watt.</b> Read-only. Value: Product-specific. Specifies in watts/TDP units the conversion factor for converting TDP units to watts. Tdp2Watt is a fixed point integer with 10 bits to the right of the decimal point and 0 bits to the left of the decimal point.                                                                                                                              |

### D18F5xEC Load Step Throttle Control

| Bits  | Description |
|-------|-------------|
| 31:19 | Reserved.   |

|      |                                                                                                                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18:7 | <b>LSCacThreshold: load step Cac threshold.</b> IF <a href="#">D18F4x15C</a> [BoostLock] THEN Read-only ELSE Read-write ENDIF. Cold reset: Product-specific. Specifies the power consumption threshold required for load step throttling. <a href="#">D18F4x1C0</a> [NodeCacLatest] must be less than LSCacThreshold prior to load step throttling. |
| 6:4  | <b>LSPstate: load step P-state.</b> Cold reset: Product-specific. IF <a href="#">D18F4x15C</a> [BoostLock] THEN Read-only ELSE Read-write ENDIF. Specifies the P-state threshold required for load step throttling. This field uses hardware P-state numbering. See <a href="#">2.5.3.1.1.2 [Hardware P-state Numbering]</a> .                      |
| 3:1  | <b>LSCpNum: load step compute unit number.</b> Cold reset: Product-specific. IF <a href="#">D18F4x15C</a> [BoostLock] THEN Read-only ELSE Read-write ENDIF. Specifies the compute unit threshold required for load step throttling. The number of compute units in C0 must be greater than LSCpNum prior to load step throttling. See LSPstate.     |
| 0    | <b>LSThrottleEn: load step throttle enable.</b> Cold reset: Product-specific. Read-write. 1=Enable the load step throttle controllers when the requirements in LSCpNum, LSPstate, and LSCacThreshold are met.                                                                                                                                       |

### D18F5x128 Clock Power/Timing Control 3

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |             |      |             |     |        |     |           |     |      |     |           |

### D18F5x16[C:0] Northbridge P-state [3:0]

Each of these registers specify the frequency and voltage associated with each of the NB P-states.

**Table 188: Register Mapping for D18F5x16[C:0]**

| Register  | Function     |
|-----------|--------------|
| D18F5x160 | NB P-state 0 |
| D18F5x164 | NB P-state 1 |
| D18F5x168 | NB P-state 2 |
| D18F5x16C | NB P-state 3 |

The NbVid field is allowed to be different between processors in a multi-processor system. All other fields are required to be programmed to the same value for all processors in the coherent fabric. See 2.5.4.1 [NB P-states] for more information about these registers.

**Table 189: NB P-state Definitions**

| Term            | Definition                                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>NBCOF</b>    | NB current operating frequency in MHz. $NBCOF = 100 * (D18F5x16[C:0][NbFid] + 4h) / (2^{D18F5x16[C:0][NbDid]})$ .                  |
| <b>NBCOF[0]</b> | NB current operating frequency in MHz for NB P-state 0.<br>$NBCOF[0] = (100 * (D18F5x160[NbFid] + 4h) / (2^{D18F5x160[NbDid]}))$ . |

**Table 189: NB P-state Definitions**

| Term            | Definition                                                                                                                                                         |

| 6:1   | <b>NbFid[5:0]: Northbridge frequency ID.</b> Read-write. Cold reset: Product-specific. Specifies the Northbridge frequency multiplier. The NB COF is a function of NbFid and NbDid, and defined by <a href="#">NBCOF</a> . NbFid and NbDid are not changed on a write if the value written results in a frequency greater than <a href="#">MSRC001_0071[MaxNbCof]</a> . See <a href="#">2.5.3.1.5 [Core P-state Transition Behavior]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |             |     |                                    |     |                                      |     |                                       |     |           |

|   |                                                                                                                                                                                                                                                                                                                                                                                              |

|------|--------------------------------------------------------------------------------------------|
| 15:8 | <b>NameStringByte1: name string ASCII character 1.</b> Read-only. Value: Product-specific. |
| 7:0  | <b>NameStringByte0: name string ASCII character 0.</b> Read-only. Value: Product-specific. |

### D18F5x240 ECC Exclusion Base Address Low

- Transaction addresses are within the defined range if:  
EccExclBaseAddr[47:6] <= address[47:6] <= EccExclLimitAddr[47:6].
- BIOS must quiesce all other forms of DRAM traffic when configuring this range. See [MSRC001\\_001F](#)[Dis-DramScrub].
- When initializing the base/limit pair, the BIOS must write the limit register before the EccExclEn bit is set. BIOS should clear EccExclEn before changing the address range.
- BIOS should take care to re-initialize memory with valid ECC when resizing this region.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:6 | <b>EccExclBaseAddr[31:6]: ECC exclusion base address register bits[31:6].</b> Read-write. Reset: 0. EccExclBaseAddr[47:6]={ <a href="#">D18F5x244</a> [EccExclBaseAddr[47:32]], EccExclBaseAddr[31:6]}. The ECC Exclusion Base/Limit Address registers setup a contiguous range in DRAM where ECC check and error reporting is disabled. BIOS configures the ECC exclusion range code to cover the frame buffer region in ECC UMA systems with internal GPUs. The GPU is configured as MC_SHARED:MC_VM_STEERING [DEFAULT_STEERING]=1 (system traffic to onion). |

**NBIOAPICx20 IRQ Pin Assertion**

| Bits | Description                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                           |
| 7:0  | <b>InputIrq.</b> Read-write. Reset: 0. IRQ number for the requested interrupt. A write to this register will trigger an interrupt associated with the redirection table entry referenced by the IRQ number. Currently the redirection table has 24 entries. Writes with IRQ number greater than 17h have no effect. |

**NBIOAPICx40 EOI**

| Bits | Description                                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                     |
| 7:0  | <b>Vector.</b> Write-only. Reset: 0. Interrupt vector. A write to this register will clear the remote IRR bit in the redirection table entry found matching the interrupt vector. This provides an alternate mechanism other than PCI special cycle for EOI to reach IOxAPIC. |

### 3.16 IOMMU Memory Mapped Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.12.1 [IOMMU Configuration Space].

#### IOMMUx00 Device Table Base Address Low

| Bits  | Description                                                                                                                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12 | <b>DevTblBase[31:12]: device table base address bits[31:12]</b> . Read-write. Reset: 0. DevTblBase[51:12] = {IOMMUx04[DevTblBase[51:32], DevTblBase[31:12]]}. DevTblBase[51:12] specifies the 4Kbyte-aligned base address of the first level device table.                         |
| 11:9  | Reserved.                                                                                                                                                                                                                                                                          |
| 8:0   | <b>DevTblSize: device table size</b> . Read-write. Reset: 0. This field contains 1 less than the length of the device table, in multiples of 4K bytes. A minimum size of 0 corresponds to a 4K byte device table and a maximum size of 1FFh corresponds to a 2M byte device table. |

#### IOMMUx04 Device Table Base Address High

| Bits  | Description                                                                                         |

| 24    | <b>SmiFLogEn: SMI filter log enable</b> . Read-write. Reset: 0. Specifies if blocked SMI interrupts are reported in the IOMMU event log. When SmiFSup=00b, SmiFLogEn is ignored by hardware and may be implemented as a read-only value of 0b. 0b=SMI interrupts are not logged in the IOMMU event log (same behavior as IOMMU Revision 1). 1b=SMI interrupts blocked due to a match-failure with all valid (SmiDV=1b) SMI filter registers are reported in the IOMMU event log. |
| 23    | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 22    | <b>SmiFEn: SMI filter enable</b> . Read-write. Reset: 0. Specifies how SMI interrupts are controlled by the IOMMU. When SmiFSup=00b, SmiFEn is ignored by hardware and may be implemented as a read-only value of 0b. 0b=SMI interrupts are always passed-through (same behavior as IOMMU Revision 1). 1b=SMI interrupts are blocked unless otherwise controlled by the SMI Filter Registers and blocked SMI interrupts are reported in the event log as governed by SmiFLogEn.  |

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 14    | <b>PprIntEn.</b> Read-write. Reset: 0. 1=An interrupt is generated when <a href="#">IOMMUx2020[PprInt]</a> =1 or <a href="#">IOMMUx2020[PprOverflow]</a> =1. The interrupt vector used is indicated in <a href="#">D0F2x50[IommuM-siNumPpr]</a> . This bit must be programmed to zero when <a href="#">IOMMUx30[PprSup]</a> =0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 13    | <b>PprLogEn.</b> Read-write. Reset: 0. 1=Peripheral page service request events are written to the peripheral page service request log when IommuEn=1. 0=Peripheral page service request logging is not enabled. Peripheral page service requests are discarded when PprLogEn=0 or <a href="#">IOMMUx30[PprSup]</a> =0. When IommuEn=1 and software sets PprLogEn, the IOMMU clears <a href="#">IOMMUx2020[PprOverflow]</a> and sets <a href="#">IOMMUx2020[PprRun]</a> . The IOMMU can then write new entries to the event log if there are usable entries available. Software can read <a href="#">IOMMUx2020[PprRun]</a> to determine the status of the peripheral page service request log. Note the peripheral page service request and event logs are independent. <a href="#">IOMMUx38</a> , <a href="#">IOMMUx2030</a> , and <a href="#">IOMMUx2038</a> must be programmed prior to setting PprLogEn. |
| 12    | <b>CmdBufEn.</b> Read-write. Reset: 0. 1=Start or restart command buffer processing. When CmdBufEn=1 and IommuEn=1, the IOMMU starts fetching commands and sets <a href="#">IOMMUx2020[CmdBufRun]</a> . 0=Halt command buffer processing. Writing a 0 to this bit causes the IOMMU to cease fetching new commands although commands previously fetched are completed. The IOMMU stops fetching commands upon reset and after errors. See <a href="#">IOMMUx2020[CmdBufRun]</a> . Writing of event log entries is independently controlled by EventLogEn. <a href="#">IOMMUx08</a> , <a href="#">IOMMUx0C</a> , <a href="#">IOMMUx2000</a> , and <a href="#">IOMMUx2008</a> must be programmed prior to setting CmdBufEn.                                                                                                                                                                                      |
| 11    | <b>Isoc.</b> Read-write. Reset: 0. This bit controls the state of the isochronous bit in the HyperTransport™ read request packet when the IOMMU issues I/O page table reads and device table reads on the HyperTransport link. 1=Request packet to use isochronous channel. 0=Request packet to use standard channel. If IOMMU isoc requests are enabled, then we must ensure the isoc channel is enabled as well. See <a href="#">D0F0x98_x1E[HiPriEn]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

This bit controls the state of the PassPW bit in the HyperTransport read request packet when the IOMMU issues I/O page table reads and device table reads on the HyperTransport link.. 1=Request packet may pass posted requests. 0=Request packet may not pass posted requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 18:4  | <b>CmdHdptr: command buffer head pointer.</b> Read-write; updated-by-hardware. Reset: 0. Specifies the 128-bit aligned offset from the command buffer base address register of the next command to be fetched by the IOMMU. The IOMMU increments this register, rolling over to zero at the end of the buffer, after fetching and validating the command in the command buffer. After incrementing this register, the IOMMU cannot re-fetch the command from the buffer. If this register is written by software while IOMMUx2020[CmdBufRun]=1, the IOMMU behavior is undefined. If this register is set by software to a value outside the length specified by IOMMUx0C[ComLen], the IOMMU behavior is undefined. |
| 3:0   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**IOMMUx2008 Command Buffer Tail Pointer**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 31:19 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 18:4  | <b>CmdTailptr: command buffer tail pointer.</b> Read-write; updated-by-hardware. Reset: 0. Specifies the 128-bit aligned offset from the command buffer base address register of the next command to be written by the software. Software must increment this field, rolling over to zero at the end of the buffer, after writing a command to the command buffer. If software advances the tail pointer equal to or beyond the head pointer after adding one or more commands to the buffer, the IOMMU behavior is undefined. If software sets the command buffer tail pointer to an offset beyond the length of the command buffer, the IOMMU behavior is undefined. |
| 3:0   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### IOMMUx2018 Event Log Tail Pointer

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:19 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 18:4  | <b>EventTailptr: event log tail pointer.</b> Read-write. Reset: 0. Specifies the 128-bit aligned offset from the event log base address register that will be written next by the IOMMU when an event is detected. The IOMMU increments this register, rolling over at the end of the buffer, after writing an event to the event log. If this register is written while <a href="#">IOMMUx2020[EventLogRun]=1</a> , the IOMMU behavior is undefined. If this register is set by software to a value outside the length specified by <a href="#">IOMMUx14[EventLen]</a> , the IOMMU behavior is undefined. |
| 3:0   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 10    | Reserved.   |
| 9     | Reserved.   |
| 8     | Reserved.   |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 | <b>PprRun: peripheral page service request running.</b> Read-only. Reset: 0. 1=PPR requests are logged as they occur. 0=PPR requests are discarded without logging.. When PprOverflow=1, the IOMMU does not write new PPR log entries even when PprRun=1. When halted, PPR request logging is restarted by using <a href="#">IOMMUx18[PprLogEn]</a> .                                                                                |
| 6 | <b>PprInt: peripheral page service request interrupt.</b> Read-write; Write-1-to-clear. Reset: 0. 1=PPR request entry written to the PPR log by the IOMMU. 0=No PPR entry written to the PPR log by the IOMMU. See <a href="#">IOMMUx18[PprIntEn]</a> .                                                                                                                                                                              |
| 5 | <b>PprOverflow: peripheral page service request overflow.</b> Read-write; Write-1-to-clear. Reset: 0. 1=IOMMU PPR log overflow has occurred. This bit is set when a new peripheral page service request is to be written to the PPR log and there is no usable entry in the PPR log, causing the new information to be discarded. No new PPR log entries are written while this bit is set. See <a href="#">IOMMUx18[PprIntEn]</a> . |
| 4 | <b>CmdBufRun: command buffer running.</b> Read-only. Reset: 0. 1=Commands may be fetched from the command buffer. 0=IOMMU has stopped fetching new commands. The IOMMU freezes command processing after <code>COMMAND_HARDWARE_ERROR</code> or <code>ILLEGAL_COMMAND_ERROR</code> errors. When frozen, command fetching is restarted by using <a href="#">IOMMUx18[CmdBufEn]</a> .                                                   |
| 3 | <b>EventLogRun: event log running.</b> Read-only. Reset: 0. 1=Events are logged as they occur.. 0=Event reports are discarded without logging. When EventOverflow=1, the IOMMU does not write new event log entries even when EventLogRun=1. When halted, event logging is restarted by using <a href="#">IOMMUx18[EventLogEn]</a> .                                                                                                 |
| 2 | <b>ComWaitInt: completion wait interrupt.</b> Read-write; Write-1-to-clear. Reset: 0. 1=COMPLETION_WAIT command completed. This bit is only set if the i bit is set in the COMPLETION_WAIT command. See <a href="#">IOMMUx18[ComWaitIntEn]</a> .                                                                                                                                                                                     |
| 1 | <b>EventLogInt: event log interrupt.</b> Read-write; Write-1-to-clear. Reset: 0. 1=Event entry written to the event log by the IOMMU. See <a href="#">IOMMUx18[EventIntEn]</a> .                                                                                                                                                                                                                                                     |
| 0 | <b>EventOverflow.</b> Read-write; Write-1-to-clear. Reset: 0. 1=IOMMU event log overflow has occurred. This bit is set when a new event is to be written to the event log and there is no usable entry in the event log, causing the new event information to be discarded. No new event log entries are written while this bit is set. See <a href="#">IOMMUx18[EventIntEn]</a> .                                                   |

### IOMMUx2030 PPR Log Head Pointer

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 18:4  | <b>PprHdptr: ppr head pointer.</b> Read-write. Reset: 0. Specifies the 128-bit aligned offset from the PPR log base address register that will be read next by software. Software must increment this field, rolling over at the end of the buffer, after reading a PPR request entry from the PPR event log. If software advances the head pointer beyond the tail pointer, the IOMMU behavior is undefined. If software sets the PPR log head pointer to an offset beyond the length of the PPR log, the IOMMU behavior is undefined. |

#### APIC30 APIC Version

| Bits  | Description                                                                                                                                                                    |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>ExtApicSpace: extended APIC register space present.</b> Read-only. Reset: 1. 1=Indicates the presence of extended APIC register space starting at <a href="#">APIC400</a> . |
| 30:25 | RAZ.                                                                                                                                                                           |
| 24    | <b>DirectedEoiSupport: directed EOI support.</b> Read-only. Reset: 0. 0=Directed EOI capability not supported.                                                                 |
| 23:16 | <b>MaxLvtEntry.</b> Read-only. Reset: Product-specific. Specifies the number of entries in the local vector table minus one.                                                   |
| 15:8  | RAZ.                                                                                                                                                                           |
| 7:0   | <b>Version.</b> Read-only. Reset: 10h. Indicates the version number of this APIC implementation.                                                                               |

#### APIC80 Task Priority (TPR)

| Bits | Description                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | RAZ.                                                                                                                                    |
| 7:0  | <b>Priority.</b> Read-write. Reset: 0. This field is assigned by software to set a threshold priority at which the core is interrupted. |

#### APIC90 Arbitration Priority (APR)

| Bits | Description                                                                                                                                                                                                                                                      |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | RAZ.                                                                                                                                                                                                                                                             |
| 7:0  | <b>Priority.</b> Read-only. Reset: 0. Indicates the current priority for a pending interrupt, or a task or interrupt being serviced by the core. The priority is used to arbitrate between cores to determine which accepts a lowest-priority interrupt request. |

**APICA0 Processor Priority (PPR)**

| Bits | Description                                                                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | RAZ.                                                                                                                                                                                                                                                                              |
| 7:0  | <b>Priority.</b> Reset: 0. Read-only. Indicates the core's current priority servicing a task or interrupt, and is used to determine if any pending interrupts should be serviced. It is the higher value of the task priority value and the current highest in-service interrupt. |

**APICB0 End of Interrupt**

This register is written by the software interrupt handler to indicate the servicing of the current interrupt is complete.

| Bits | Description         |
|------|---------------------|
| 31:0 | Unused. Write-only. |

**APICC0 Remote Read**

| Bits | Description                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>RemoteReadData.</b> Read-only. Reset: 0. The data resulting from a valid completion of a remote read inter-processor interrupt. |

**APICD0 Logical Destination (LDR)**

| Bits  | Description                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Destination.</b> Read-write. Reset: 0. This APIC's destination identification. Used to determine which interrupts should be accepted. |
| 23:0  | Reserved.                                                                                                                                |

**APICE0 Destination Format**

Only supported in xAPIC mode.

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                               |             |                   |    |                               |       |          |    |                            |

| 11:10 | RAZ.                                                                                                                                                                                                                                                                                                                                                                 |
| 9     | <b>FocusDisable.</b> Read-write. Reset: 0. 1=Disable focus core checking during lowest-priority arbitrated interrupts.                                                                                                                                                                                                                                               |
| 8     | <b>APICSWEn: APIC software enable.</b> Read-write. Reset: 0. 0=SMI, NMI, INIT, LINT[1:0], and Startup interrupts may be accepted; pending interrupts in <a href="#">APIC[170:100]</a> and <a href="#">APIC[270:200]</a> are held, but further fixed, lowest-priority, and ExtInt interrupts are not accepted. All LVT entry mask bits are set and cannot be cleared. |
| 7:0   | <b>Vector.</b> Read-write. Reset: FFh. The vector that is sent to the core in the event of a spurious interrupt. The behavior of bits 3:0 are controlled as specified by <a href="#">D18F0x68[ApicExtSpur]</a> .                                                                                                                                                     |

### APIC[170:100] In-Service (ISR)

The in-service registers provide a bit per interrupt to indicate that the corresponding interrupt is being serviced by the core. APIC100[15:0] are reserved. Interrupts are mapped as follows:

Table 203: [Register Mapping](#) for [APIC\[170:100\]](#)

| Register | Function             |
|----------|----------------------|
| APIC100  | Interrupts [31:16]   |
| APIC110  | Interrupts [63:32]   |
| APIC120  | Interrupts [95:64]   |
| APIC130  | Interrupts [127:96]  |
| APIC140  | Interrupts [159:128] |
| APIC150  | Interrupts [191:160] |
| APIC160  | Interrupts [223:192] |
| APIC170  | Interrupts [255:224] |

| Bits | Description                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>InServiceBits.</b> Reset: 0. Read-only. These bits are set when the corresponding interrupt is being serviced by the core. |

### APIC[1F0:180] Trigger Mode (TMR)

The trigger mode registers provide a bit per interrupt to indicate the assertion mode of each interrupt. APIC180[15:0] are reserved. Interrupts are mapped as follows:

Table 204: [Register Mapping](#) for APIC[1F0:180]

| Register | Function             |
|----------|----------------------|
| APIC180  | Interrupts [31:16]   |
| APIC190  | Interrupts [63:32]   |
| APIC1A0  | Interrupts [95:64]   |
| APIC1B0  | Interrupts [127:96]  |
| APIC1C0  | Interrupts [159:128] |
| APIC1D0  | Interrupts [191:160] |
| APIC1E0  | Interrupts [223:192] |
| APIC1F0  | Interrupts [255:224] |

| Bits | Description                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>TriggerModeBits</b> . Reset: 0. Read-only. The corresponding trigger mode bit is updated when an interrupt is accepted. The values are: 0=Edge-triggered interrupt. 1=Level-triggered interrupt. |

### APIC[270:200] Interrupt Request (IRR)

The interrupt request registers provide a bit per interrupt to indicate that the corresponding interrupt has been accepted by the APIC. APIC200[15:0] are reserved. Interrupts are mapped as follows:

Table 205: [Register Mapping](#) for APIC[270:200]

| Register | Function             |
|----------|----------------------|
| APIC200  | Interrupts [31:16]   |
| APIC210  | Interrupts [63:32]   |
| APIC220  | Interrupts [95:64]   |
| APIC230  | Interrupts [127:96]  |
| APIC240  | Interrupts [159:128] |
| APIC250  | Interrupts [191:160] |
| APIC260  | Interrupts [223:192] |
| APIC270  | Interrupts [255:224] |

| Bits | Description                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>RequestBits</b> . Read-only. Reset: 0. The corresponding request bit is set when the an interrupt is accepted by the APIC. |

### APIC280 Error Status

Writes to this register trigger an update of the register state. The value written by software is arbitrary. Each write causes the internal error state to be loaded into this register, clearing the internal error state. Consequently, a second write prior to the occurrence of another error causes the register to be overwritten with cleared data.

| Bits | Description |
|------|-------------|
| 31:8 | RAZ.        |

|     |                                                                                                                                                                                                                 |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | <b>IllegalRegAddr: illegal register address.</b> Read-write. Reset: 0. This bit indicates that an access to a nonexistent register location within this APIC was attempted. Can only be set in xAPIC mode.      |
| 6   | <b>RcvdIllegalVector: received illegal vector.</b> Read-write. Reset: 0. This bit indicates that this APIC has received a message with an illegal vector (00h to 0Fh for fixed and lowest priority interrupts). |
| 5   | <b>SentIllegalVector.</b> Read-write. Reset: 0. This bit indicates that this APIC attempted to send a message with an illegal vector (00h to 0Fh for fixed and lowest priority interrupts).                     |
| 4   | RAZ.                                                                                                                                                                                                            |
| 3   | <b>RcvAcceptError: receive accept error.</b> Read-write. Reset: 0. This bit indicates that a message received by this APIC was not accepted by this or any other APIC.                                          |
| 2   | <b>SendAcceptError.</b> Read-write. Reset: 0. This bit indicates that a message sent by this APIC was not accepted by any APIC.                                                                                 |
| 1:0 | RAZ.                                                                                                                                                                                                            |

### APIC300 Interrupt Command Low (ICR Low)

Not all combinations of ICR fields are valid. Only the following combinations are valid:

**Table 206: ICR valid combinations**

| Message Type                    | Trigger Mode | Level  | Destination Shorthand              |
|---------------------------------|--------------|--------|------------------------------------|
| Fixed                           | Edge         | x      | x                                  |
|                                 | Level        | Assert | x                                  |
| Lowest Priority, SMI, NMI, INIT | Edge         | x      | Destination or all excluding self. |
|                                 | Level        | Assert | Destination or all excluding self  |
| Startup                         | x            | x      | Destination or all excluding self  |

Note: x indicates a don't care.

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                    |     |                                  |     |      |     |                    |     |                                                                                                                                                                            |

| 31:3 | RAZ.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2    | <b>ExtApicIdEn: extended APIC ID enable</b> . Read-write. Reset: 0. 1=Enable 8-bit APIC ID; <a href="#">APIC20[ApicId]</a> supports an 8-bit value; an interrupt broadcast in physical destination mode requires that the <code>IntDest[7:0]=1111_1111b</code> (instead of <code>xxxx_1111b</code> ); a match in physical destination mode occurs when <code>(IntDest[7:0] == ApicId[7:0])</code> instead of <code>(IntDest[3:0] == ApicId[3:0])</code> . If <code>ExtApicIdEn=1</code> then program <a href="#">D18F0x68[ApicExtId]=1</a> and <a href="#">D18F0x68[ApicExtBrdCst]=1</a> . |

|   |                                                                                                                                                |
|---|------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | <b>SeoiEn.</b> Read-write. Reset: 0. 1=Enable SEOI generation when a write to <a href="#">APIC420 [Specific End Of Interrupt]</a> is received. |
| 0 | <b>IerEn.</b> Read-write. Reset: 0. 1=Enable writes to the interrupt enable registers.                                                         |

### APIC420 Specific End Of Interrupt

| Bits | Description                                                                                                                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | RAZ.                                                                                                                                                                                                                                                                  |
| 7:0  | <b>EoiVec: end of interrupt vector.</b> Read-write. Reset: 0. A write to this field causes an end of interrupt cycle to be performed for the vector specified in this field. The behavior is undefined if no interrupt is pending for the specified interrupt vector. |

### APIC[4F0:480] Interrupt Enable

Interrupt enables range is mapped as follows:

Table 209: [Register Mapping](#) for APIC[4F0:480]

| Register | Function       |
|----------|----------------|
| APIC480  | IntEn[31:0]    |
| APIC490  | IntEn[63:32]   |
| APIC4A0  | IntEn[95:64]   |
| APIC4B0  | IntEn[127:96]  |
| APIC4C0  | IntEn[159:128] |
| APIC4D0  | IntEn[191:160] |
| APIC4E0  | IntEn[223:192] |
| APIC4F0  | IntEn[255:224] |

| Bits | Description                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>InterruptEnableBits.</b> Read-write. Reset: FFFF_FFFFh. The interrupt enable bits can be used to enable each of the 256 interrupts. See above table. |

### APIC[530:500] Extended Interrupt [3:0] Local Vector Table

APIC500 provides a local vector table entry for IBS; See [D18F3x1CC](#). APIC510 provides a local vector table entry for error thresholding. The APIC[530:520] registers are unused.

Table 210: [Register Mapping](#) for APIC[530:500]

| Register | Function                            |
|----------|-------------------------------------|
| APIC500  | Extended Interrupt 0 (IBS)          |
| APIC510  | Extended Interrupt 1 (Thresholding) |
| APIC520  | Extended Interrupt 2                |
| APIC530  | Extended Interrupt 3                |

| Bits  | Description                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:17 | RAZ.                                                                                                                                                                          |
| 16    | <b>Mask.</b> Read-write. Reset: 1. 0=Not masked. 1=Masked.                                                                                                                    |
| 15:13 | RAZ.                                                                                                                                                                          |
| 12    | <b>DS: interrupt delivery status.</b> Read-only; updated-by-hardware. Reset: 0. 0=Idle. 1=Send pending. (Indicates that the interrupt has not yet been accepted by the core.) |
| 11    | RAZ.                                                                                                                                                                          |
| 10:8  | <b>MsgType: message type.</b> Read-write. Reset: 000b. See <a href="#">2.4.9.1.14 [Generalized Local Vector Table]</a> .                                                      |
| 7:0   | <b>Vector.</b> Read-write. Reset: 00h. Interrupt vector number.                                                                                                               |

### 3.18 CPUID Instruction Registers

Processor feature capabilities and configuration information are provided through the CPUID instruction. The information is accessed by (1) selecting the CPUID function setting EAX and optionally ECX for some functions, (2) executing the CPUID instruction, and (3) reading the results in the EAX, EBX, ECX, and EDX registers. The syntax *CPUID FnXXXX\_XXXX\_EiX[\_xYYY]* refers to the function where EAX==X, and optionally ECX==Y, and the registers specified by EiX. EiX can be any single register such as {EAX, EBX, ECX, and EDX}, or a range of registers, such as E[C,B,A]X. Undefined function numbers return 0's in all 4 registers. See [2.4.11 \[CPUID Instruction\]](#).

Unless otherwise specified, single-bit feature fields are encoded as 1=Feature is supported by the processor; 0=Feature is not supported by the processor.

The following provides processor specific details about CPUID.

#### **CPUID Fn0000\_0000\_EAX Processor Vendor and Largest Standard Function Number**

| Bits | Description                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>LFuncStd: largest standard function.</b> Value: 0000_000Dh. The largest CPUID standard function input value supported by the processor implementation. |

#### **CPUID Fn0000\_0000\_E[D,C,B]X Processor Vendor**

[CPUID Fn0000\\_0000\\_E\[D,C,B\]X](#) and [CPUID Fn8000\\_0000\\_E\[D,C,B\]X](#) return the same value.

**Table 211: Reset Mapping for [CPUID Fn8000\\_0000\\_E\[D,C,B\]X](#)**

| Register              | Value      | Description                     |
|-----------------------|------------|---------------------------------|
| CPUID Fn0000_0000_EBX | 6874_7541h | The ASCII characters “h t u A”. |
| CPUID Fn0000_0000_ECX | 444D_4163h | The ASCII characters “D M A c”. |
| CPUID Fn0000_0000_EDX | 6974_6E65h | The ASCII characters “i t n e”. |

| Bits | Description                                                                            |
|------|----------------------------------------------------------------------------------------|
| 31:0 | <b>Vendor.</b> The 12 8-bit ASCII character codes to create the string “AuthenticAMD”. |

**CPUID Fn0000\_0001\_EAX Family, Model, Stepping Identifiers**

Also see [CPUID Fn8000\\_0001\\_EAX \[Family, Model, Stepping Identifiers\]](#).

**Family** is an 8-bit value and is defined as: **Family[7:0]** = ({0000b, BaseFamily[3:0]} + ExtendedFamily[7:0]). E.g. If BaseFamily[3:0]=Fh and ExtendedFamily[7:0]=07h, then Family[7:0]=16h.

**Model** is an 8-bit value and is defined as: **Model[7:0]** = {ExtendedModel[3:0], BaseModel[3:0]}. E.g. If ExtendedModel[3:0]=Eh and BaseModel[3:0]=8h, then Model[7:0] = E8h. Model numbers vary with product.

| Bits  | Description                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31:28 | Reserved.                                                                                                                                |
| 27:20 | <b>ExtFamily: extended family.</b> <a href="#">CPUID Fn0000_0001_EAX[ExtFamily]</a> is an alias of <a href="#">D18F3xFC[ExtFamily]</a> . |
| 19:16 | <b>ExtModel: extended model.</b> <a href="#">CPUID Fn0000_0001_EAX[ExtModel]</a> is an alias of <a href="#">D18F3xFC[ExtModel]</a> .     |
| 15:12 | Reserved.                                                                                                                                |
| 11:8  | <b>BaseFamily.</b> <a href="#">CPUID Fn0000_0001_EAX[BaseFamily]</a> is an alias of <a href="#">D18F3xFC[BaseFamily]</a> .               |
| 7:4   | <b>BaseModel.</b> <a href="#">CPUID Fn0000_0001_EAX[BaseModel]</a> is an alias of <a href="#">D18F3xFC[BaseModel]</a> .                  |
| 3:0   | <b>Stepping.</b> <a href="#">CPUID Fn0000_0001_EAX[Stepping]</a> is an alias of <a href="#">D18F3xFC[Stepping]</a> .                     |

**CPUID Fn0000\_0001\_EBX LocalApicId, LogicalProcessorCount, CLFlush**

| Bits  | Description                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>LocalApicId: initial local APIC physical ID.</b> The initial <a href="#">APIC20[ApicId]</a> value. See <a href="#">2.4.4 [Processor Cores and Downcoring]</a> .                                            |
| 23:16 | <b>LogicalProcessorCount: logical processor count.</b> Value: <a href="#">CPUID Fn8000_0008_ECX[NC]</a> + 1. Specifies the number of cores in the processor as <a href="#">CPUID Fn8000_0008_ECX[NC]</a> + 1. |
| 15:8  | <b>CLFlush: CLFLUSH size in quadwords.</b> Value: 08h.                                                                                                                                                        |
| 7:0   | <b>8BitBrandId: 8 bit brand ID.</b> Value: 00h. Indicates that the brand ID is in <a href="#">CPUID Fn8000_0001_EBX</a> .                                                                                     |

**CPUID Fn0000\_0001\_ECX Feature Identifiers**
